Abstract – In this paper, the characteristics of a small antenna using an H-shaped microstrip patch are studied. Significant reduction in antenna size can be realized when the H-shaped patch is used instead of the conventional rectangular microstrip patch antenna. The theoretical analysis will be carried out based on the finite-difference time-domain (FDTD) method, optimization of output of this microstrip patch antenna will be done using Genetic algorithm scheme, in order to find best results. The FDTD programs can be developed and validated by available measurement results. The effects of various parameters of antenna on the resonant frequency and radiation patterns will be used to carry out results. Several design curves should be used, which are useful for practical antenna design. The current distributions on the patch and those on the ground plane are described together with the results illustrating the electric field distributions under the patch. This antenna is appropriate for applications where small size and broad beam-width are required.

Keywords – Microstrip Patch Antenna, FDTD, Genetic Algorithm Scheme.
